

SUPPLEMENTARY MATERIAL

Methods

Sample collection and processing

Blood draws contributing to these analyses were conducted at the fourth assessment wave of the PATH study. Samples were collected after a fast of at least 8 hours, stored at -80C aliquoted in 1ml vials. Immediately prior to analysis samples were thawed, diluted 1:2 (except total tau: 1:1), and were all processed with the same pipeline at the same time at the ANU Phenomics Facility. All markers were assessed in duplicates in plasma as recommended by assay manufacturers (Mesoscale, Rockville, USA). Controls included in kits were compared to the manufacturer's guide range, and the robustness of the data was confirmed by the manufacturer.

Inflammatory cytokines and OS markers

TNF α , TNF-R1, TNF-R2, IL1 β , IL4, IL6, IL8, IL10 were measured on the Mesoscale platform with the human high sensitivity cytokine and pro-inflammatory panel 1 assays (Rockville, MD, USA). Other measures were assessed on ELISA assays as follows: NO (ELISA OxiSelect™, Jomar Bioscience, STA-802), Neo (Human BioAssay, Jomar Biosciences, #3410), TAC (Abcam, #Ab65329), MDA (ELISA OxiSelect™, Jomar Bioscience, STA-832), GUA (Oxidative Damage EIA kit, Sapphire Biosciences, #190-58932). The mean coefficient of variation across all assays was 16.7% (range 0.91%-49.3%). IL1 α was also assayed but did not pass quality control and therefore was not included in analyses.

AD Biomarkers

Amyloid beta 38, 40, and 42 as well as total tau were measured on the Mesoscale platform with the human high sensitivity V-PLEX Plus A β Peptide Panel 1 assay (Rockville, MD, USA). The mean coefficient of variation across all assays was 9.84% (range 2.33%-14.30%).

Principal component analysis

Pearson bivariate correlations are presented in **Figure S1** and indicate that none of the markers were exclusively positively or negatively associated with other measures. TNF-R1 and TNF-R2 were the most highly correlated measures. Notably, the shared variance between pairs of markers was on average relatively low and ranged from 0.04% to 23% (with one exception TNF-R1 & TNF-R2 at 69% in the 40s and 74% in the 60s). NO, GUA and TAC shared least variance with other markers while IL6 and IL10 shared most variance in the 40s, and IL4 and IL8 in the 60s.

Table S1. Factor loadings of OS/inflammatory markers on each principal component in the 40s.

```

Table S3. Association between C-Reactive Protein (CRP) and inflammatory states identified in the PCA. Note that CRP has been log transformed to account for extreme kurtosis. Results were consistent regardless of covariates, coefficients reported here come from models controlling for gender, age, education, hypertensive status, type 2 diabetes status, Goldberg depression inventory, BMI, and smoking (pack years).
