The MB molecule liquid-solid equilibrium can be modelled by Equation (S1):

$$C_s = \frac{K_L S_m C_L}{1 + K_L C_L} \quad (S1)$$

where  $C_s$  is the amount of MB adsorbed on the solid surface at equilibrium (mol/g),  $C_L$  is the concentration of MB in the surnatant (mol/L),  $S_m$  is the apparent sorption capacity or adsorption maximum (mol/g) and  $K_L$  is the Langmuir coefficient (g/mol). The experimental points follow the adsorption Langmuir isotherm, where the amount of absorbed MB converges towards an equilibrium value. Since every MB molecule covers  $1,3 \text{ nm}^2$  area, the SSA can be directly obtained once the total number of MB molecules adsorbed on the sample is known.

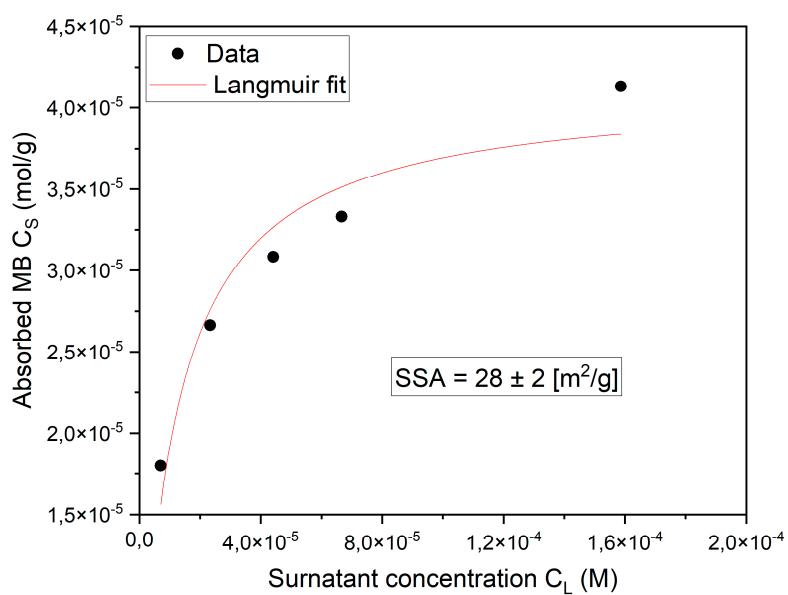

Figure S1. Langmuir isotherm fit for BC1 sample.
